

WARNING: FETAL TOXICITY

- **When pregnancy is detected, discontinue Averothiazide as soon as possible.**
- **Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.**

Averothiazide

Averothiazide 10 mg/12.5 mg/40 mg film-coated tablets

Averothiazide 5 mg/25 mg/40 mg film-coated tablets

Averothiazide 5 mg/12.5 mg/40 mg film-coated tablets

Averothiazide 5 mg/12.5 mg/20 mg film-coated tablets

Clinical particulars

Therapeutic indications

Treatment of essential hypertension.

Add-on therapy

Averothiazide is indicated in adult patients whose blood pressure is not adequately controlled on the combination of olmesartan medoxomil and amlodipine taken as dual-component formulation.

Substitution therapy

Averothiazide is indicated as substitution therapy in adult patients whose blood pressure is adequately controlled on the combination of olmesartan medoxomil, amlodipine and hydrochlorothiazide, taken as a dual-component (olmesartan medoxomil and amlodipine or olmesartan medoxomil and hydrochlorothiazide) and a single-component formulation (hydrochlorothiazide or amlodipine).

Posology and method of administration

Posology

Adults

The recommended dose of Averothiazide is 1 tablet per day.

Add-on therapy

Averothiazide 20 mg/5 mg/12.5 mg may be administered in patients whose blood pressure is not adequately controlled on olmesartan medoxomil 20 mg and amlodipine 5 mg taken as dual-component combination.

Averothiazide 40 mg/5 mg/12.5 mg may be administered in patients whose blood pressure is not adequately controlled on olmesartan medoxomil 20 mg and amlodipine 5 mg taken as dual-component combination.

Averothiazide 40 mg/5 mg/25 mg may be administered in patients whose blood pressure is not adequately controlled on Averothiazide 40 mg/5 mg/12.5 mg.

Averothiazide 40 mg/10 mg/12.5 mg may be administered in patients whose blood pressure is not adequately controlled on olmesartan medoxomil 40 mg and amlodipine 10 mg taken as dual-component combination or by Averothiazide 40 mg/5 mg/12.5 mg.

A step-wise titration of the dosage of the individual components is recommended before changing to the triple-component combination. When clinically appropriate, direct change from dual-component combination to the triple-component combination may be considered.

Substitution therapy

Patients controlled on stable doses of olmesartan medoxomil, amlodipine and hydrochlorothiazide taken at the same time as a dual-component (olmesartan medoxomil and amlodipine or olmesartan medoxomil and hydrochlorothiazide) and a single-component formulation (hydrochlorothiazide or amlodipine) may be switched to Averothiazide containing the same component doses.

The maximum recommended dose of Averothiazide is 40 mg/10 mg/25 mg per day.

Older people (age 65 years or over)

Caution, including more frequent monitoring of blood pressure, is recommended in elderly people, particularly at the maximum dose of Averothiazide 40 mg/10 mg/25 mg per day.

An increase of the dosage should take place with care in elderly people (see sections Special warnings and precautions for use and Pharmacokinetic properties).

Very limited data are available on the use of Averothiazide in patients aged 75 years or older. Extreme caution, including more frequent monitoring of blood pressure, is recommended.

Renal impairment

The maximum dose in patients with mild to moderate renal impairment (creatinine clearance of 30 – 60 mL/min) is Averothiazide 20 mg/5 mg/12.5 mg, owing to limited experience of the 40 mg olmesartan medoxomil dosage in this patient group.

Monitoring of serum concentrations of potassium and creatinine is advised in patients with moderate renal impairment.

The use of Averothiazide in patients with severe renal impairment (creatinine clearance < 30 mL/min) is contraindicated (see sections contraindications, Special warnings and precautions for use and Pharmacokinetic properties).

Hepatic impairment

Averothiazide should be used with caution in patients with mild hepatic impairment (see sections Special warnings and precautions for use and Pharmacokinetic properties).

In patients with moderate hepatic impairment the maximum dose should not exceed Averothiazide 20 mg/5 mg/12.5 mg once daily. Close monitoring of blood pressure and renal function is advised in patients with hepatic impairment.

As with all calcium antagonists, amlodipine's half-life is prolonged in patients with impaired liver function and dosage recommendations have not been established. Averothiazide should therefore be administered with caution in these patients. The pharmacokinetics of amlodipine have not been studied

in severe hepatic impairment. Amlodipine should be initiated at the lowest dose and titrated slowly in patients with impaired liver function.

Use of Averothiazide is contraindicated in patients with severe hepatic impairment (see sections contraindications and Pharmacokinetic properties), cholestasis or biliary obstruction (see section contraindications).

Pediatrics population

Averothiazide is not recommended for use in patients aged below 18 years due to a lack of data on safety and efficacy.

Method of administration:

The tablet should be swallowed with a sufficient amount of fluid (e. g. one glass of water). The tablet should not be chewed and should be taken at the same time each day.

Averothiazide can be taken with or without food.

Contraindications

- 1- Hypersensitivity to the active substances, to dihydropyridine derivates or to sulfonamide-derived substances (since hydrochlorothiazide is a sulfonamide-derived drug) or to any of the excipients.
- 2- Severe renal impairment (see sections special warnings and precautions for use and section pharmacokinetic properties).
- 3- Refractory hypokalaemia, hypercalcaemia, hyponatraemia and symptomatic hyperuricaemia.
- 4- Severe hepatic insufficiency, cholestasis and biliary obstructive disorders (see section pharmacokinetic properties).
- 5- 2nd and 3rd trimester of pregnancy (see sections Special warnings and precautions for use and Fertility, pregnancy and lactation).
- 6- The concomitant use of Averothiazide with aliskiren-containing products is contraindicated in patients with diabetes mellitus or renal impairment (GFR < 60 mL/min/1.73 m²) (see sections Interaction with other medicinal products and other forms of interaction and Pharmacodynamic properties).
- 7- Due to the amlodipine component, Averothiazide is contraindicated in patients with:
 - Shock (including cardiogenic shock).
 - Severe hypotension
 - Obstruction of the outflow tract of the left ventricle (e.g. high grade aortic stenosis).
 - Haemodynamically unstable heart failure after acute myocardial infarction.

Special warnings and precautions for use

- 1- Infections

Cytomegalovirus (CMV) infections including cases of CMV reactivation have been reported in LEMTRADA-treated patients. Most cases occurred within 2 months of alemtuzumab dosing. Before initiation of therapy, evaluation of immune serostatus could be considered according to local guidelines.

2- Patients with hypovolemia or sodium depletion:

Symptomatic hypotension may occur in patients who are volume and/or sodium depleted as a result of vigorous diuretic therapy, dietary salt restriction, diarrhoea or vomiting, especially after the first dose. Correction of this condition prior to administration of Averothiazide or close medical supervision at the start of the treatment is recommended.

3- Other conditions with stimulation of the renin-angiotensin-aldosterone system:

In patients whose vascular tone and renal function depend predominantly on the activity of the renin-angiotensin-aldosterone system (e. g. patients with severe congestive heart failure or underlying renal disease, including renal artery stenosis), treatment with medicinal products that affect this system has been associated with acute hypotension, azotemia, oliguria or, rarely, acute renal failure.

4- Renovascular hypertension:

There is an increased risk of severe hypotension and renal insufficiency when patients with bilateral renal artery stenosis or stenosis of the artery to a single functioning kidney are treated with medicinal products that affect the renin-angiotensin-aldosterone system.

5- Renal impairment and kidney transplantation:

When Averothiazide is used in patients with impaired renal function, periodic monitoring of serum concentrations of potassium and creatinine is recommended.

Use of Averothiazide is not recommended in patients with severe renal impairment (creatinine clearance < 30 mL/min) (see sections Posology and method of administration, Contraindications and pharmacokinetic properties).

Thiazide diuretic-associated azotemia may occur in patients with impaired renal function.

If progressive renal impairment becomes evident, careful reappraisal of therapy is necessary, with consideration given to discontinuing diuretic therapy.

There is no experience of the administration of Averothiazide in patients with a recent kidney transplant or in patients with end-stage renal impairment (i. e. creatinine clearance < 12 mL/min).

6- Dual blockade of the renin-angiotensin-aldosterone system (RAAS):

There is evidence that the concomitant use of ACE-inhibitors, angiotensin II receptor blockers or aliskiren increases the risk of hypotension, hyperkalemia and decreased renal function (including acute renal failure). Dual blockade of RAAS through the combined use of ACE-inhibitors, angiotensin II receptor blockers or aliskiren is therefore not recommended (see sections Interaction with other medicinal products and other forms of interaction and Pharmacodynamic properties).

If dual blockade therapy is considered absolutely necessary, this should only occur under specialist supervision and subject to frequent close monitoring of renal function, electrolytes and blood pressure.

ACE-inhibitors and angiotensin II receptor blockers should not be used concomitantly in patients with diabetic nephropathy.

7- Hepatic impairment:

Exposure to amlodipine and olmesartan medoxomil is increased in patients with hepatic impairment (see section pharmacokinetic properties).

Furthermore, minor alterations of fluid and electrolyte balance during thiazide therapy may precipitate hepatic coma in patients with impaired hepatic function or progressive liver disease.

Care should be taken when Averothiazide is administered in patients with mild to moderate hepatic impairment.

In patients with moderate hepatic impairment, the dose of olmesartan medoxomil should not exceed 20 mg (see sections Posology and method of administration)

In patients with impaired hepatic function, amlodipine should be initiated at the lower end of the dosing range and caution should be used, both on initial treatment and when increasing the dose.

Use of Averothiazide is contraindicated in patients with severe hepatic impairment, cholestasis or biliary obstruction (see section contraindications).

8- Aortic and mitral valve stenosis, obstructive hypertrophic cardiomyopathy:

Due to the amlodipine component of Averothiazide HCT, as with other vasodilators, special caution is indicated in patients suffering from aortic or mitral stenosis, or obstructive hypertrophic cardiomyopathy.

9- Primary aldosteronism:

Patients with primary aldosteronism generally will not respond to anti-hypertensive medicinal products acting through inhibition of the renin-angiotensin system. Therefore, the use of Averothiazide is not recommended in such patients.

10- Metabolic and endocrine effects:

Thiazide therapy may impair glucose tolerance. In diabetic patients dosage adjustments of insulin or oral hypoglycemic agents may be required (see section Interaction with other medicinal products and other forms of interaction) Latent diabetes mellitus may become manifest during thiazide therapy.

Increases in cholesterol and triglyceride levels are undesirable effects known to be associated with thiazide diuretic therapy.

Hyperuricaemia may occur or frank gout may be precipitated in some patients receiving thiazide therapy.

11- Electrolyte imbalance:

As for any patient receiving diuretic therapy, periodic determination of serum electrolytes should be performed at appropriate intervals.

Thiazides, including hydrochlorothiazide, can cause fluid or electrolyte imbalance (including hypokalemia, hypernatremia and hypochloraemic alkalosis). Warning signs of fluid or electrolyte imbalance are dryness of the mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pain or cramps, muscle fatigue, hypotension, oliguria, tachycardia, and gastrointestinal disturbances such as nausea or vomiting (see section undesirable effects).

The risk of hypokalemia is greatest in patients with cirrhosis of the liver, in patients experiencing brisk diuresis, in patients who are receiving inadequate oral intake of electrolytes and in patients receiving concomitant therapy with corticosteroids or ACTH (see section Interaction with other medicinal products and other forms of interaction).

Conversely, due to antagonism at the angiotensin-II receptors (AT1) through the olmesartan medoxomil component of Averothiazide hyperkalemia may occur, especially in the presence of renal impairment and/or heart failure, and diabetes mellitus. Close monitoring of serum potassium in patients at risk is recommended. Potassium-sparing diuretics, potassium supplements or potassium-containing salt substitutes and other medicinal products that may increase serum potassium levels (e. g. heparin) should be co-administered cautiously with Averothiazide (see section Interaction with other medicinal products and other forms of interaction) and with frequent monitoring of potassium levels.

There is no evidence that olmesartan medoxomil would reduce or prevent diuretic-induced hyponatremia. Chloride deficit is generally mild and usually does not require treatment.

Thiazides may decrease urinary calcium excretion and cause an intermittent and slight elevation of serum calcium in the absence of known disorders of calcium metabolism.

Hypocalcaemia may be evidence of hidden hyperparathyroidism. Thiazides should be discontinued before carrying out tests for parathyroid function.

Thiazides have been shown to increase the urinary excretion of magnesium, which may result in hypomagnesaemia.

Dilutional hyponatremia may occur in edematous patients in hot weather.

12- Lithium:

As with other angiotensin II receptor antagonists, the coadministration of Averothiazide and lithium is not recommended (see section Interaction with other medicinal products and other forms of interaction).

13- Heart failure:

As a consequence of the inhibition of the renin-angiotensin-aldosterone system, changes in renal function may be anticipated in susceptible individuals.

In patients with severe heart failure whose renal function may depend on the activity of the renin-angiotensin-aldosterone system, treatment with angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor antagonists has been associated with oliguria and/or progressive azotemia and (rarely) with acute renal failure and/or death.

Patients with heart failure should be treated with caution. In a long-term, placebo controlled study of amlodipine in patients with severe heart failure (NYHA III and IV), the reported incidence of pulmonary edema was higher in the amlodipine group than in the placebo group (see section pharmacodynamic properties). Calcium channel blockers, including amlodipine, should be used with caution in patients with congestive heart failure, as they may increase the risk of future cardiovascular events and mortality.

14- Sprue-like enteropathy:

In very rare cases severe, chronic diarrhea with substantial weight loss has been reported in patients taking olmesartan few months to years after drug initiation, possibly caused by a localized delayed hypersensitivity reaction. Intestinal biopsies of patients often demonstrated villous atrophy. If a patient develops these symptoms during treatment with olmesartan, exclude other etiologies, olmesartan

treatment should be immediately discontinued and should not be restarted. If diarrhoea does not improve during the week after the discontinuation, further specialist (e.g. a gastro-enterologist) advice should be considered.

15- Acute Myopia and Secondary Angle-Closure Glaucoma

Hydrochlorothiazide, a sulfonamide, can cause an idiosyncratic reaction, resulting in acute transient myopia and acute angle-closure glaucoma. Symptoms include acute onset of decreased visual acuity or ocular pain and typically occur within hours to weeks of drug initiation. Untreated acute angle-closure glaucoma can lead to permanent vision loss. The primary treatment is to discontinue hydrochlorothiazide as rapidly as possible. Prompt medical or surgical treatments may need to be considered if the intraocular pressure remains uncontrolled. Risk factors for developing acute angle-closure glaucoma may include a history of sulfonamide or penicillin allergy (see section undesirable effects).

16- Pregnancy:

Angiotensin II receptor antagonists should not be initiated during pregnancy. Unless continued angiotensin II receptor antagonists therapy is considered essential, patients planning pregnancy should be changed to alternative anti-hypertensive treatments which have an established safety profile for use in pregnancy. When pregnancy is diagnosed, treatment with angiotensin II receptor antagonists should be stopped immediately, and, if appropriate, alternative therapy should be started (see sections contraindications and Fertility, pregnancy and lactation).

17- Paediatric population:

Averothiazide is not indicated in children and adolescents under the age of 18 years.

18- Older people:

In older people, increase of the dosage should take place with care (see section pharmacokinetics properties).

19- Photosensitivity:

Cases of photosensitivity reactions have been reported with thiazide diuretics (see section undesirable effects). If photosensitivity reaction occurs during treatment with Averothiazide HCT, it is recommended to stop the treatment. If re-administration of the diuretic is deemed necessary, it is recommended to protect the areas exposed to the sun or to artificial UVA.

20- Non-melanoma skin cancer:

An increased risk of non-melanoma skin cancer (NMSC) [basal cell carcinoma (BCC) and squamous cell carcinoma (SCC)] with increasing cumulative dose of hydrochlorothiazide (HCTZ) exposure has been observed in two epidemiological studies based on the Danish National Cancer Registry. Photosensitizing actions of HCTZ could act as a possible mechanism for NMSC.

Patients taking HCTZ should be informed of the risk of NMSC and advised to regularly check their skin for any new lesions and promptly report any suspicious skin lesions. Possible preventive measures such as limited exposure to sunlight and UV rays and, in case of exposure, adequate protection should be advised to the patients in order to minimize the risk of skin cancer. Suspicious skin lesions should be

promptly examined potentially including histological examinations of biopsies. The use of HCTZ may also need to be reconsidered in patients who have experienced previous NMSC (see section undesirable effects).

21- Other:

As with any antihypertensive agent, excessive blood pressure reduction in patients with ischemic heart disease or ischemic cerebrovascular disease could result in a myocardial infarction or stroke.

Hypersensitivity reactions to hydrochlorothiazide may occur in patients with or without a history of allergy or bronchial asthma, but are more likely in patients with such a history.

Exacerbation or activation of systemic lupus erythematosus has been reported with the use of thiazide diuretics.

As with all other angiotensin II receptor antagonists, the blood pressure lowering effect of olmesartan is somewhat less in black patients than in non-black patients, however, this effect was not seen in one of the three clinical trials with olmesartan that included black patients (30 %) see also section pharmacodynamic properties.

This medicine contains less than 1 mmol sodium (23 mg) per film-coated tablet, that is to say essentially 'sodium-free'.

Interaction with other medicinal products and other forms of interaction

Potential interactions related to the Averothiazide combination:

Concomitant use not recommended

Lithium:

Reversible increases in serum lithium concentrations and toxicity have been reported during concomitant administration of lithium with angiotensin converting enzyme inhibitors and, rarely, with angiotensin II receptor antagonists. In addition, renal clearance of lithium is reduced by thiazides and consequently the risk of lithium toxicity may be increased. Therefore use of Averothiazide and lithium in combination is not recommended (see section Special warnings and precautions for use) if use of the combination proves necessary, careful monitoring of serum lithium levels is recommended.

Concomitant use requiring caution

- Baclofen:

Potential of antihypertensive effect may occur.

- Non-steroidal anti-inflammatory medicinal products:

NSAIDs (i.e. acetylsalicylic acid (> 3 g/day), COX-2 inhibitors and non-selective NSAIDs) may reduce the antihypertensive effect of thiazide diuretics and angiotensin II receptor antagonists.

In some patients with compromised renal function (e. g. dehydrated patients or older people with compromised renal function) the co-administration of angiotensin II receptor antagonists and agents that inhibit cyclooxygenase may result in further deterioration of renal function, including possible acute renal failure, which is usually reversible. Therefore, the combination should be administered with

caution, especially in older people. Patients should be adequately hydrated and consideration should be given to monitoring of renal function after initiation of concomitant therapy and periodically thereafter.

Concomitant use to be taken into account

- Amifostine:

Potential of antihypertensive effect may occur.

- Other antihypertensive agents:

The blood pressure lowering effect of Averothiazide can be increased by concomitant use of other antihypertensive medicinal products.

- Alcohol, barbiturates, narcotics or antidepressants:

Potential of orthostatic hypotension may occur.

Potential interactions related to olmesartan medoxomil:

Concomitant use not recommended

- ACE-inhibitors, angiotensin II receptor blockers or aliskiren:

Clinical trial data has shown that dual blockade of the renin-angiotensin-aldosterone-system (RAAS) through the combined use of ACE-inhibitors, angiotensin II receptor blockers or aliskiren is associated with a higher frequency of adverse events such as hypotension, hyperkalemia and decreased renal function (including acute renal failure) compared to the use of a single RAAS-acting agent (see sections contraindications, Special warnings and precautions for use and pharmacodynamic properties).

- Medicinal products affecting potassium levels:

Concomitant use of potassium-sparing diuretics, potassium supplements, and salt substitutes containing potassium or other medicinal products that may increase serum potassium levels (e. g. heparin, ACE inhibitors) may lead to increases in serum potassium (see section Special warnings and precautions for use) If medicinal products that affect potassium are to be prescribed in combination with Averothiazide, monitoring of serum potassium is advised.

Additional information

Bile acid sequestering agent Colesevelam:

Concurrent administration of the bile acid sequestering agent colesevelam hydrochloride reduces the systemic exposure and peak plasma concentration of olmesartan and reduces $t_{1/2}$. Administration of olmesartan medoxomil at least 4 hours prior to colesevelam hydrochloride decreased the drug interaction effect. Administering olmesartan medoxomil at least 4 hours before the colesevelam hydrochloride dose should be considered (see section pharmacokinetic properties).

After treatment with antacid (aluminum magnesium hydroxide), a modest reduction in bioavailability of olmesartan was observed.

Olmesartan medoxomil had no significant effect on the pharmacokinetics or pharmacodynamics of warfarin or the pharmacokinetics of digoxin.

Coadministration of olmesartan medoxomil with pravastatin had no clinically relevant effects on the pharmacokinetics of either component in healthy subjects.

Olmesartan had no clinically relevant inhibitory effects on human cytochrome P450 enzymes 1A1/2, 2A6, 2C8/9, 2C19, 2D6, 2E1 and 3A4 *in vitro*, and had no or minimal inducing effects on rat cytochrome

P450 activities. No clinically relevant interactions between olmesartan and medicinal products metabolized by the above cytochrome P450 enzymes are expected.

Potential interactions related to amlodipine

Concomitant use requiring caution

Effects of other medicinal products on amlodipine

- CYP3A4 inhibitors:

Concomitant use of amlodipine with strong or moderate CYP3A4 inhibitors (protease inhibitors, azole antifungals, macrolides like erythromycin or clarithromycin, verapamil or diltiazem) may give rise to significant increase in amlodipine exposure. The clinical translation of these pharmacokinetic variations may be more pronounced in older people. Clinical monitoring and dose adjustment may thus be required.

- CYP3A4 inducers:

Upon co-administration of known inducers of the CYP3A4, the plasma concentration of amlodipine may vary. Therefore, blood pressure should be monitored and dose regulation considered both during and after concomitant medication particularly with strong CYP3A4 inducers (e.g. rifampicin, hypericum perforatum).

Administration of amlodipine with grapefruit or grapefruit juice is not recommended as bioavailability may be increased in some patients resulting in increased blood pressure lowering effects.

Dantrolene (infusion): In animals, lethal ventricular fibrillation and cardiovascular collapse are observed in association with hyperkalemia after administration of verapamil and intravenous dantrolene. Due to risk of hyperkalemia, it is recommended that the co-administration of calcium channel blockers such as amlodipine be avoided in patients susceptible to malignant hyperthermia and in the management of malignant hyperthermia.

Effects of amlodipine on other medicinal products

The blood pressure-lowering effect of amlodipine adds to the blood pressure-lowering effects of other antihypertensive agents.

In clinical interaction studies, amlodipine did not affect the pharmacokinetics of atorvastatin, digoxin or warfarin.

Simvastatin: Co-administration of multiple doses of 10 mg of amlodipine with 80 mg simvastatin resulted in a 77% increase in exposure to simvastatin compared to simvastatin alone. Limit the dose of simvastatin in patients on amlodipine to 20 mg daily.

Tacrolimus: There is a risk of increased tacrolimus blood levels when co-administered with amlodipine. In order to avoid toxicity of tacrolimus, administration of amlodipine in a patient treated with tacrolimus requires monitoring of tacrolimus blood levels and dose adjustment of tacrolimus when appropriate.

Cyclosporine: In a prospective study in renal transplant patients, an average 40% increase in trough cyclosporine levels was observed when used concomitantly with amlodipine. The co-administration of

Averothiazide with cyclosporine may increase exposure to cyclosporine. Monitor trough cyclosporine levels during concomitant use and cyclosporine dose reductions should be made as necessary.

Potential interactions related to hydrochlorothiazide:

Concomitant use not recommended

Medicinal products affecting potassium levels:

The potassium-depleting effect of hydrochlorothiazide (see section special warning and precautions for use) may be potentiated by the coadministration of other medicinal products associated with potassium loss and hypokalemia (e. g. other kaliuretic diuretics, laxatives, corticosteroids, ACTH, amphotericin, carbenoxolone, penicillin G sodium or salicylic acid derivatives). Such concomitant use is therefore not recommended.

Concomitant use requiring caution

- Calcium salts:

Thiazide diuretics may increase serum calcium owing to decreased excretion. If calcium supplements must be prescribed, serum calcium should be monitored and calcium dosage adjusted accordingly.

- Cholestyramine and colestipol resins:

Absorption of hydrochlorothiazide is impaired in the presence of anionic exchange resins.

- Digitalis glycosides:

Thiazide-induced hypokalemia or hypomagnesaemia may favor the onset of digitalis-induced cardiac arrhythmias.

- Medicinal products affected by serum potassium disturbances:

Periodic monitoring of serum potassium and ECG is recommended when Averothiazide is administered with medicinal products affected by serum potassium disturbances (e. g. digitalis glycosides and antiarrhythmic) and with the following torsade's de pointes (ventricular tachycardia)-inducing medicinal products (including some antiarrhythmic), hypokalemia being a predisposing factor to torsade's de pointes (ventricular tachycardia):

- Class Ia antiarrhythmic (e. g. quinidine, hydroquinidine, disopyramide).
- Class III antiarrhythmic (e. g. amiodarone, sotalol, dofetilide, ibutilide).
- Some antipsychotics (e. g. thioridazine, chlorpromazine, levomepromazine, trifluoperazine, cyamemazine, sulpiride, sultopride, amisulpride, tiapride, pimozide, haloperidol, droperidol).
- Others (e. g. bepridil, cisapride, diphemanil, erythromycin IV, halofantrin, mizolastin, pentamidine, sparfloxacin, terfenadine, vincamine IV).

- Non-depolarizing skeletal muscle relaxants (e. g. tubocurarine):

The effect of nondepolarizing skeletal muscle relaxants may be potentiated by hydrochlorothiazide.

- Anticholinergic agents (e. g. atropine, biperiden):

Increase of the bioavailability of thiazide-type diuretics by decreasing gastrointestinal motility and stomach emptying rate.

- Antidiabetic medicinal products (oral agents and insulin):

The treatment with a thiazide may influence the glucose tolerance. Dosage adjustment of the antidiabetic medicinal product may be required (see section special precautions and warning for use).

- Metformin:

Metformin should be used with caution because of the risk of lactic acidosis induced by possible functional renal failure linked to hydrochlorothiazide.

- Beta-blockers and diazoxide:

The hyperglycemic effect of beta-blockers and diazoxide may be enhanced by thiazides.

- Pressor amines (e. g. noradrenaline):

The effect of pressor amines may be decreased.

- Medicinal products used in the treatment of gout (e. g. probenecid, sulfinpyrazone and allopurinol):
Dosage adjustment of uricosuric medicinal products may be necessary since hydrochlorothiazide may raise the level of serum uric acid. Increase in dosage of probenecid or sulfinpyrazone may be necessary. Coadministration of a thiazide may increase the incidence of hypersensitivity reactions to allopurinol.

- Amantadine:

Thiazides may increase the risk of adverse effects caused by amantadine.

- Cytotoxic agents (e. g. cyclophosphamide, methotrexate):

Thiazides may reduce the renal excretion of cytotoxic medicinal products and potentiate their myelosuppressive effects.

- Salicylates:

In case of high dosages of salicylates hydrochlorothiazide may enhance the toxic effect of the salicylates on the central nervous system.

- Methyldopa:

There have been isolated reports of haemolytic anemia occurring with concomitant use of hydrochlorothiazide and methyldopa.

- Cyclosporine:

Concomitant treatment with cyclosporine may increase the risk of hyperuricaemia and gout-type complications.

- Tetracyclines:

Concomitant administration of tetracyclines and thiazides increases the risk of tetracycline-induced increase in urea. This interaction is probably not applicable to doxycycline.

Fertility, pregnancy and lactation

Pregnancy

The use of Averothiazide is contra-indicated during the 2nd and 3rd trimester of pregnancy (see sections contraindications and special precautions and warning for use). Given the effects of the individual components in this combination product on pregnancy, the use of Averothiazide is not recommended during the first trimester of pregnancy (see section special precautions and warning for use).

- **Olmesartan medoxomil**

The use of angiotensin II receptor antagonists is not recommended during the first trimester of pregnancy (see section special precautions and warning for use). The use of angiotensin II receptor antagonists is contra-indicated during the 2nd and 3rd trimester of pregnancy (see sections contraindications and special precautions and warning for use).

Epidemiological evidence regarding the risk of teratogenicity following exposure to ACE inhibitors during the first trimester of pregnancy has not been conclusive; however a small increase in risk cannot be excluded. Whilst there is no controlled epidemiological data on the risk with angiotensin II receptor antagonists, similar risks may exist for this class of drugs. Unless continued angiotensin receptor blocker therapy is considered essential, patients planning pregnancy should be changed to alternative anti-hypertensive treatments, which have an established safety profile for use in pregnancy. When pregnancy is diagnosed, treatment with angiotensin II receptor antagonists should be stopped immediately, and, if appropriate, alternative therapy should be started.

Exposure to angiotensin II receptor antagonists therapy during the 2nd and 3rd trimesters is known to induce human fetotoxicity (decreased renal function, oligohydramnios, skull ossification retardation) and neonatal toxicity (renal failure, hypotension, and hyperkalaemia).

Should exposure to angiotensin II receptor antagonists have occurred from the 2nd trimester of pregnancy, ultrasound check of renal function and skull is recommended.

Infants, whose mothers have taken angiotensin II receptor antagonists should be closely observed for hypotension (see sections contraindications and special precautions and warning for use).

- **Hydrochlorothiazide**

There is limited experience with hydrochlorothiazide during pregnancy, especially during the first trimester. Animal studies are insufficient.

Hydrochlorothiazide crosses the placenta. Based on the pharmacological mechanism of action of hydrochlorothiazide its use during the 2nd and 3rd trimester may compromise foeto-placental perfusion and may cause foetal and neonatal effects like icterus, disturbance of electrolyte balance and thrombocytopenia.

Hydrochlorothiazide should not be used for gestational oedema, gestational hypertension or pre-eclampsia due to the risk of decreased plasma volume and placental hypoperfusion, without a beneficial effect on the course of the disease.

Hydrochlorothiazide should not be used for essential hypertension in pregnant women except in rare situations where no other treatment could be used.

- **Amlodipine**

Data on a limited number of exposed pregnancies do not indicate that amlodipine or other calcium receptor antagonists have a harmful effect on the health of the fetus. However, there may be a risk of prolonged delivery.

Breast-feeding

During breastfeeding, Averoethiazide is not recommended and alternative treatments with better established safety profiles during breastfeeding are preferable, especially while nursing a newborn or preterm infant.

Olmesartan is excreted into the milk of lactating rats. However, it is not known whether olmesartan passes into human milk.

Amlodipine is excreted in human milk. The proportion of the maternal dose received by the infant has been estimated with an interquartile range of 3 - 7%, with a maximum of 15%. The effect of amlodipine on infants is unknown.

Hydrochlorothiazide is excreted in human milk in small amounts. Thiazides in high doses causing intense diuresis can inhibit the milk production.

The use of Averoethiazide during breastfeeding is not recommended. If Averoethiazide is used during breastfeeding, doses should be kept as low as possible.

Fertility

Reversible biochemical changes in the head of spermatozoa have been reported in some patients treated by calcium channel blockers.

Clinical data are insufficient regarding the potential effect of amlodipine on fertility. In one rat study, adverse effects were found on male fertility.

Effects on ability to drive and use machines

No studies on the effects on the ability to drive and use machines have been performed.

However, it should be borne in mind that dizziness, headache, nausea or fatigue may occasionally occur in patients taking antihypertensive therapy and that these symptoms may impair the ability to react. Caution is recommended especially at the start of treatment.

Undesirable effects

The most commonly reported adverse reactions during treatment with olmesartan medoxomil, amlodipine and hydrochlorothiazide are peripheral edema, headache and dizziness.

The following terminologies have been used in order to classify the occurrence of undesirable effects:

Very common ($\geq 1/10$)

Common ($\geq 1/100$ to $< 1/10$)

Uncommon ($\geq 1/1,000$ to $< 1/100$)

Rare ($\geq 1/10,000$ to $< 1/1,000$)

Very rare ($< 1/10,000$)

Not known (cannot be estimated from the available data)

Table 1: Overview of adverse reactions with Averoethiazide and the single components.

MedDRA System Organ Class	Adverse reactions	Frequency			
		AVERTHIAZIDE	Olmesartan	Amlodipine	HCTZ
Infections and infestations	Upper respiratory tract infection	Common			
	Nasopharyngitis	Common			
	Urinary tract infection	Common	Common		
	Sialadenitis				Rare
	Cytomegalovirus infection				uncommon
Neoplasms benign, malignant and unspecified (incl cysts and polyps)	Non-melanoma skin cancer (Basal cell carcinoma and Squamous cell carcinoma)			Not known	
Blood and lymphatic system disorders	Leucopenia			Very rare	Rare
	Thrombocytopenia		Uncommon	Very rare	Rare
	Bone marrow depression				Rare
	Neutropenia/Agranulocytosis				Rare
	Haemolytic anemia				Rare
	Aplastic anemia				Rare
Immune system disorders	Anaphylactic reaction		Uncommon		
	Drug hypersensitivity			Very rare	
Metabolism and nutrition disorders	Hyperkalemia	Uncommon	Rare		
	Hypokalemia	Uncommon			Common
	Anorexia				Uncommon
	Glycosuria				Common
	Hypocalcaemia				Common
	Hyperglycaemia			Very rare	Common
	Hypomagnesaemia				Common
	Hyponatraemia				Common
	Hypochloraemia				Common
	Hypertriglyceridaemia		Common		Very common
	Hypercholesterolaemia				Very common

	Hyperuricaemia		Common		Very common
	Hypochloraemic alkalosis				Very rare
	Hyperamylasaemia				Common
Psychiatric disorders	Confusional state			Rare	Common
	Depression			Uncommon	Rare
	Apathy				Rare
	Irritability			Uncommon	
	Restlessness				Rare
	Mood changes (including anxiety)			Uncommon	
	Sleep disorders (including insomnia)			Uncommon	Rare
Nervous system disorders	Dizziness	Common	Common	Common	Common
	Headache	Common	Common	Common	Rare
	Postural dizziness	Uncommon			
	Presyncope	Uncommon			
	Dysgeusia			Uncommon	
	Hypertonia			Very rare	
	Hypoesthesia			Uncommon	
	Paresthesia			Uncommon	Rare
	Peripheral neuropathy			Very rare	
	Somnolence			Common	
	Syncope			Uncommon	
	Convulsions				Rare
	Loss of appetite				Uncommon
	Tremor			Uncommon	
	Extrapyramidal disorder			Not known	
Eye disorders	Visual disturbance (including diplopia, blurred vision)			Uncommon	Rare
	Lacrimation decreased				Rare
	Worsening of myopia				Uncommon
	Xanthopsia				Rare

	Acute myopia, acute angle-closure glaucoma (see section special precautions and warning for use)				Not known
Ear and labyrinth disorders	Vertigo	Uncommon	Uncommon		Rare
	Tinnitus			Uncommon	
Cardiac disorders	Palpitations	Common		Uncommon	
	Tachycardia	Uncommon			
	Myocardial infarction			Very rare	
	Arrhythmia (including bradycardia, ventricular tachycardia and atrial fibrillation)			Very rare	Rare
	Angina pectoris		Uncommon	Uncommon (incl. aggravation of angina pectoris)	
Vascular disorders	Hypotension	Common	Rare	Uncommon	
	Flushing	Uncommon		Common	
	Orthostatic hypotension				Uncommon
	Vasculitis (including necrotising angiitis)			Very rare	Rare
	Thrombosis				Rare
	Embolism				Rare
Respiratory, thoracic and mediastina disorders	Cough	Uncommon	Common	Very rare	
	Bronchitis		Common		
	Dyspnoea			Uncommon	Rare
	Pharyngitis		Common		
	Rhinitis		Common	Uncommon	
	Acute interstitial pneumonia				Rare
	Respiratory distress				Uncommon
	Pulmonary edema				Rare
	Diarrhea	Common	Common		Common

Gastrointestinal disorders	Nausea	Common	Common	Common	Common
	Constipation	Common			Common
	Dry mouth	Uncommon		Uncommon	
	Abdominal pain		Common	Common	Common
	Altered bowel habits (including diarrhea and constipation)			Uncommon	
	Meteorism				Common
	Dyspepsia		Common	Uncommon	
	Gastritis			Very rare	
	Gastric irritation				Common
	Gastroenteritis		Common		
	Gingival hyperplasia			Very rare	
	Paralytic ileus				Very rare
	Pancreatitis			Very rare	Rare
	Vomiting		Uncommon	Uncommon	Common
	Sprue-like enteropathy (see section special precautions and warning for use)		Very rare		
Hepato-biliary disorders	Hepatitis			Very rare	
	Jaundice (intrahepatic cholestasis icterus)			Very rare	Rare
	Acute cholecystitis				Rare
Skin and subcutaneous tissue disorders	Alopecia			Uncommon	
	Angioedema		Rare	Very rare	
	Allergic dermatitis		Uncommon		
	Erythema multiforme			Very rare	
	Erythema				Uncommon
	Cutaneous lupus erythematoses-like reactions				Rare
	Exanthema		Uncommon	Uncommon	
	Exfoliative dermatitis			Very rare	
	Hyperhidrosis			Uncommon	
	Photosensitivity reactions			Very rare	Uncommon

	Pruritus		Uncommon	Uncommon	Uncommon
	Purpura			Uncommon	Uncommon
	Quincke oedema			Very rare	
	Rash		Uncommon	Uncommon	Uncommon
	Reactivation of cutaneous lupus erythematoses				Rare
	Toxic epidermal necrolysis				Rare
	Skin discoloration			Uncommon	
	Stevens-Johnson syndrome			Very rare	
	Urticaria		Uncommon	Very rare	Uncommon
Musculoskeletal and connective tissue disorders	Muscle spasm	Common	Rare	Uncommon	
	Joint swelling	Common			
	Muscular weakness	Uncommon			Rare
	Ankle swelling			Common	
	Arthralgia			Uncommon	
	Arthritis		Common		
	Back pain		Common	Uncommon	
	Paresis				Rare
	Myalgia		Uncommon	Uncommon	
	Skeletal pain		Common		
Renal and urinary disorders	Pollakiuria	Common			
	Increased urinary frequency			Uncommon	
	Acute renal failure		Rare		
	Hematuria		Common		
	Micturition disorder			Uncommon	
	Nocturia			Uncommon	
	Interstitial nephritis				Rare
	Renal insufficiency		Rare		Rare
Reproductive system and breast disorders	Erectile dysfunction	Uncommon		Uncommon	Uncommon
	Gynaecomastia			Uncommon	
	Asthenia	Common	Uncommon	Uncommon	

General disorders and administration site conditions	Peripheral oedema	Common	Common		
	Fatigue	Common	Common	Common	
	Chest pain		Common	Uncommon	
	Fever				Rare
	Influenza-like symptoms		Common		
	Lethargy		Rare		
	Malaise		Uncommon	Uncommon	
	Oedema			Common	
	Pain		Common	Uncommon	
	Face oedema		Uncommon		
Investigations	Blood creatinine increased	Common	Rare		Common
	Blood urea increased	Common	Common		Common
	Blood uric acid increased	Common			
	Blood potassium decreased	Uncommon			
	Gamma glytamyl transferase increased	Uncommon			
	Alanine aminotransferase increased	Uncommon			
	Aspartate aminotransferase increased	Uncommon			
	Hepatic enzymes increased		Common	Very rare (mostly consistent with cholestatis)	
	Blood creatine phosphokinase increased		Common		
	Weight decrease			Uncommon	
Weight increase			Uncommon		

Single cases of rhabdomyolysis have been reported in temporal association with the intake of angiotensin II receptor blockers.

Single cases of extrapyramidal syndrome have been reported in patients treated with amlodipine.

Non-melanoma skin cancer: Based on available data from epidemiological studies, cumulative dose-dependent association between HCTZ and NMSC has been observed (see also sections special precautions and warning for use and pharmacodynamic properties).

Further adverse reactions reported in clinical trials or from post marketing experience with a fixed-dose combination of olmesartan medoxomil and amlodipine and not already reported for olmesartan medoxomil,

amlodipine and hydrochlorothiazide, olmesartan medoxomil monotherapy or amlodipine monotherapy or reported in a higher frequency for the dual combination (Table 2):

Table 2: Combination of olmesartan medoxomil and amlodipine		
System Organ Class	Frequency	Adverse reactions
Immune system disorders	Rare	Drug hypersensitivity
Gastrointestinal disorders	Uncommon	Upper abdominal pain
Reproductive system and breast disorders	Uncommon	Libido decreased
General disorders and administration site conditions	Common	Pitting oedema
	Uncommon	Lethargy
Musculoskeletal and connective tissue disorders	Uncommon	Pain in extremity

Further adverse reactions reported in clinical trials or from post marketing experience with a fixed-dose combination of olmesartan medoxomil and hydrochlorothiazide and not already reported for olmesartan medoxomil, amlodipine and hydrochlorothiazide, olmesartan medoxomil monotherapy or hydrochlorothiazide monotherapy or reported in a higher frequency for the dual combination (Table 3):

Table 3: Combination of olmesartan medoxomil and hydrochlorothiazide		
System Organ Class	Frequency	Adverse reactions
Nervous system disorders	Rare	Disturbances in consciousness (such as loss of consciousness)
Skin and subcutaneous tissue disorders	Uncommon	Eczema
Musculoskeletal and connective tissue disorders	Uncommon	Pain in extremity
Investigations	Rare	Minor decreases in mean hemoglobin and hematocrit values

Reporting of suspected adverse reactions

Reporting suspected adverse reactions after authorization of the medicinal product is Important. It allows continued monitoring of the benefit/risk balance of the medicinal Product. Healthcare professionals are asked to report any suspected adverse reactions via:

E-mail:

avs@averroespharma.net

regi@averroes-eg.com

Or on the following address:

Block No 6048, 6th industrial zone Sadat city, Egypt. Tel: 0482630201/2, Fax: 0482630203

55 Hafez badawy street Nasr city, Egypt.

Also you can report via:

Egyptian Pharmaceutical Vigilance Center (EPVC)

21 Abd El Aziz Al Soud Street. El-Manial, Cairo, Egypt.

E-mail: pv.center@eda.mohp.gov.eg

Fax Number: +2 02 23684194

Telephone: +2 02 (23648046, 23640368, 23684381, 23684288), Extension No. 1303

Overdose

Symptoms:

The maximum dose of Averothiazide is 40 mg/10 mg/25 mg once daily. There is no information on overdosage with Averothiazide in humans. The most likely effect of Averothiazide overdosage is hypotension.

The most likely effects of olmesartan medoxomil overdosage are hypotension and tachycardia; bradycardia could be encountered if parasympathetic (vagal) stimulation occurred.

Amlodipine overdosage can be expected to lead to excessive peripheral vasodilatation with marked hypotension and possibly a reflex tachycardia. Marked and potentially prolonged systemic hypotension, up to and including shock with fatal outcome, has been reported.

Overdosage with hydrochlorothiazide is associated with electrolyte depletion (hypokalemia, hypochloroemia) and dehydration resulting from excessive diuresis.

The most common signs and symptoms of overdose are nausea and somnolence. Hypokalemia may result in muscle spasm and/or accentuate cardiac arrhythmias associated with the concomitant use of digitalis glycosides or certain anti-arrhythmic medicinal products.

Treatment:

In the event of overdosage with Averothiazide, treatment should be symptomatic and supportive. Management depends upon the time since ingestion and the severity of the symptoms.

If intake is recent, gastric lavage may be considered. In healthy subjects, the administration of activated charcoal immediately or up to 2 hours after ingestion of amlodipine has been shown to reduce substantially the absorption of amlodipine.

Clinically significant hypotension due to an overdose of Averothiazide requires active support of the cardiovascular system, including close monitoring of heart and lung function, elevation of the extremities, and attention to circulating fluid volume and urine output. A vasoconstrictor may be helpful in restoring vascular tone and blood pressure, provided that there is no contraindication to its use. Intravenous calcium gluconate may be beneficial in reversing the effects of calcium channel blockade.

Serum electrolytes and creatinine should be monitored frequently. If hypotension occurs, the patient should be placed in a supine position, with salt and volume replacements given quickly.

Since amlodipine is highly protein-bound, dialysis is not likely to be of benefit. The dialysability of olmesartan or hydrochlorothiazide is unknown.

The degree to which olmesartan and hydrochlorothiazide are removed by hemodialysis has not been established.

Pharmacological properties

Pharmacodynamics properties

Pharmacotherapeutic group: Angiotensin II antagonists, calcium channel blockers and diuretics.

Averothiazide is a combination of an angiotensin II receptor antagonist, olmesartan medoxomil, a calcium channel blocker, amlodipine besilate and a thiazide diuretic, hydrochlorothiazide. The combination of these ingredients has an additive antihypertensive effect, reducing blood pressure to a greater degree than each component alone.

Olmesartan medoxomil is an orally active, selective angiotensin II receptor (type AT₁) antagonist. Angiotensin II is the primary vasoactive hormone of the renin-angiotensin-aldosterone system and plays a significant role in the pathophysiology of hypertension. The effects of angiotensin II include vasoconstriction, stimulation of the synthesis and release of aldosterone, cardiac stimulation and renal reabsorption of sodium. Olmesartan blocks the vasoconstrictor and aldosterone-secreting effects of angiotensin II by blocking its binding to the AT₁ receptor in tissues including vascular smooth muscle and the adrenal gland. The action of olmesartan is independent of the source or route of synthesis of angiotensin II. The selective antagonism of the angiotensin II (AT₁) receptors by olmesartan results in increases in plasma renin levels and angiotensin I and II concentrations, and some decrease in plasma aldosterone concentrations.

In hypertension, olmesartan medoxomil causes a dose-dependent, long-lasting reduction in arterial blood pressure. There has been no evidence of first-dose hypotension, of tachyphylaxis during long-term treatment, or of rebound hypertension after abrupt cessation of therapy.

Once daily dosing with olmesartan medoxomil provides an effective and smooth reduction in blood pressure over the 24 hour dose interval.

Once daily dosing produced similar decreases in blood pressure as twice daily dosing at the same total daily dose.

With continuous treatment, maximum reductions in blood pressure are achieved by 8 weeks after the initiation of therapy, although a substantial proportion of the blood pressure lowering effect is already observed after 2 weeks of treatment.

The effect of olmesartan medoxomil on mortality and morbidity is not yet known.

The amlodipine component of Averothiazide is a calcium channel blocker that inhibits the transmembrane influx of calcium ions through the potential-dependent L-type channels into the heart and smooth muscle. Experimental data indicate that amlodipine binds to both dihydropyridine and non-dihydropyridine binding sites. Amlodipine is relatively vessel-selective, with a greater effect on vascular smooth muscle cells than on cardiac muscle cells. The antihypertensive effect of amlodipine derives from a direct relaxant effect on arterial smooth muscle, which leads to a lowering of peripheral resistance and hence of blood pressure.

In hypertensive patients, amlodipine causes a dose-dependent, long-lasting reduction in arterial blood pressure. There has been no evidence of first-dose hypotension, of tachyphylaxis during long-term treatment, or of rebound hypertension after abrupt cessation of therapy.

Following administration of therapeutic doses to patients with hypertension, amlodipine produces an effective reduction in blood pressure in the supine, sitting and standing positions. Chronic use of amlodipine is not associated with significant changes in heart rate or plasma catecholamine levels. In hypertensive patients with normal renal function, therapeutic doses of amlodipine reduce renal vascular resistance and increase glomerular filtration rate and effective renal plasma flow, without changing filtration fraction or proteinuria.

Hydrochlorothiazide is a thiazide diuretic. The mechanism of the antihypertensive effect of thiazide diuretics is not fully known. Thiazides affect the renal tubular mechanisms of electrolyte reabsorption, directly increasing excretion of sodium and chloride in approximately equivalent amounts. The diuretic action of hydrochlorothiazide reduces plasma volume, increases plasma renin activity and increases aldosterone secretion, with consequent increases in urinary potassium and bicarbonate loss, and decreases in serum potassium. The renin-aldosterone link is mediated by angiotensin II and therefore coadministration of an angiotensin II receptor antagonist tends to reverse the potassium loss associated with thiazide diuretics. With hydrochlorothiazide, onset of diuresis occurs at about 2 hours and peak effect occurs at about 4 hours post-dose, whilst the action persists for approximately 6-12 hours.

Epidemiological studies have shown that long-term treatment with hydrochlorothiazide monotherapy reduces the risk of cardiovascular mortality and morbidity.

The antihypertensive effect of Averothiazide was similar irrespective of age and gender, and was similar in patients with and without diabetes.

ACE-inhibitors and angiotensin II receptor blockers should therefore not be used concomitantly in patients with diabetic nephropathy.

Pharmacokinetic properties

Concomitant administration of olmesartan medoxomil, amlodipine and hydrochlorothiazide had no clinically-relevant effects on the pharmacokinetics of either component in healthy subjects.

Following oral administration of Averothiazide in normal healthy adults, peak plasma concentrations of olmesartan, amlodipine and hydrochlorothiazide are reached in about 1.5 to 3 hours, 6 to 8 hours, and 1.5 to 2 hours, respectively. The rate and extent of absorption of olmesartan medoxomil, amlodipine and hydrochlorothiazide from Averothiazide are the same as when administered as a dual-fixed combination of olmesartan medoxomil and amlodipine together with a hydrochlorothiazide single-component tablet or when administered as a dual-fixed combination of olmesartan medoxomil and hydrochlorothiazide together with an amlodipine single-component tablet with the same dosages. Food does not affect the bioavailability of Averothiazide.

Olmesartan medoxomil:

Absorption and distribution:

Olmesartan medoxomil is a prodrug. It is rapidly converted to the pharmacologically active metabolite, olmesartan, by esterases in the gut mucosa and in portal blood during absorption from the gastrointestinal tract. No intact olmesartan medoxomil or intact side chain medoxomil moiety have been detected in plasma or excreta. The mean absolute bioavailability of olmesartan from a tablet formulation was 25.6%.

The mean peak plasma concentration (C_{max}) of olmesartan is reached within about 2 hours after oral dosing with olmesartan medoxomil, and olmesartan plasma concentrations increase approximately linearly with increasing single oral doses up to about 80 mg.

Food had minimal effect on the bioavailability of olmesartan and therefore olmesartan medoxomil may be administered with or without food.

No clinically relevant gender-related differences in the pharmacokinetics of olmesartan have been observed. Olmesartan is highly bound to plasma protein (99.7%), but the potential for clinically significant protein binding displacement interactions between olmesartan and other highly bound co-administered active substances is low (as confirmed by the lack of a clinically significant interaction between olmesartan medoxomil and warfarin). The binding of olmesartan to blood cells is negligible. The mean volume of distribution after intravenous dosing is low (16 – 29 L).

Biotransformation and elimination:

Total plasma clearance of olmesartan was typically 1.3 L/h (CV 19%) and was relatively slow compared to hepatic blood flow (ca 90 L/h). Following a single oral dose of ¹⁴C-labelled olmesartan medoxomil, 10 - 16% of the administered radioactivity was excreted in the urine (the vast majority within 24 hours of dose administration) and the remainder of the recovered radioactivity was excreted in the faeces. Based on the systemic availability of 25.6%, it can be calculated that absorbed olmesartan is cleared by both renal excretion (ca 40%) and hepato-biliary excretion (ca 60%). All recovered radioactivity was identified as olmesartan. No other significant metabolite was detected. Enterohepatic recycling of olmesartan is minimal. Since a large proportion of olmesartan is excreted via the biliary route, use in patients with biliary obstruction is contraindicated (see section contraindications).

The terminal elimination half-life of olmesartan varied between 10 and 15 hours after multiple oral dosing. Steady state was reached after 2-5 days of dosing and no further accumulation was evident after 14 days of repeated dosing. Renal clearance was approximately 0.5 – 0.7 L/h and was independent of dose.

Drug interactions:

Bile acid sequestering agent colesevelam:

Concomitant administration of 40 mg olmesartan medoxomil and 3750 mg colesevelam hydrochloride in healthy subjects resulted in 28% reduction in C_{max} and 39% reduction in AUC of olmesartan. Lesser effects, 4% and 15% reduction in C_{max} and AUC respectively, were observed when olmesartan medoxomil was administered 4 hours prior to colesevelam hydrochloride. Elimination half-life of olmesartan was reduced by 50 – 52% irrespectively of whether administered concomitantly or 4 hours prior to colesevelam hydrochloride (see section Interaction with other medicinal products and other forms of interaction)

Amlodipine:

Absorption and distribution:

After oral administration of therapeutic doses, amlodipine is well absorbed with peak blood levels between 6-12 hours post dose. Absolute bioavailability has been estimated to be between 64 and 80%. The volume of distribution is approximately 21 l/kg. In vitro studies have shown that approximately 97.5% of circulating amlodipine is bound to plasma proteins.

The absorption of amlodipine is unaffected by the concomitant intake of food.

Biotransformation and elimination:

The terminal plasma elimination half-life is about 35-50 hours and is consistent with once daily dosing. Amlodipine is extensively metabolized by the liver to inactive metabolites with 10% of the parent compound and 60% of metabolites excreted in the urine.

Hydrochlorothiazide:

Absorption and distribution:

Following oral administration of olmesartan medoxomil and hydrochlorothiazide in combination, the median time to peak concentrations of hydrochlorothiazide was 1.5 to 2 hours after dosing. Hydrochlorothiazide is 68% protein bound in the plasma and its apparent volume of distribution is 0.83 – 1.14 L/kg.

Biotransformation and elimination:

Hydrochlorothiazide is not metabolized in man and is excreted almost entirely as unchanged active substance in urine. About 60% of the oral dose is eliminated as unchanged active substance within 48 hours. Renal clearance is about 250 – 300 mL/min. The terminal elimination half-life of hydrochlorothiazide is 10 – 15 hours.

Pharmacokinetics in special populations

1- Paediatric Population:

It has waived an obligation to submit the results of studies with olmesartan medoxomil, amlodipine and hydrochlorothiazide in all subsets of the pediatric population in essential hypertension.

2- Older people (age 65 years or over):

In hypertensive patients, the olmesartan AUC at steady state was increased by ca 35% in older people (65 – 75 years old) and by ca 44% in very old people (≥ 75 years old) compared with the younger age group (see section posology and method of administration).

This may be at least in part related to a mean decrease in renal function in this group of patients. The recommended dosage regimen for older people is, however, the same, although caution should be exercised when increasing the dosage.

The time to reach peak plasma concentrations of amlodipine is similar in older and younger subjects. Amlodipine clearance tends to be decreased with resulting increases in AUC and elimination half-life in older people. Increases in AUC and elimination half-life in patients with congestive heart failure were as expected for the patient age group in this study.

Limited data suggest that the systemic clearance of hydrochlorothiazide is reduced in both healthy and hypertensive older people compared to young healthy volunteers.

3- Renal impairment:

In renally impaired patients, the olmesartan AUC at steady state increased by 62%, 82% and 179% in patients with mild, moderate and severe renal impairment, respectively, compared to healthy controls (see sections posology and method of administration and special precautions and warning for use). The pharmacokinetics of olmesartan medoxomil in patients undergoing hemodialysis has not been studied.

Amlodipine is extensively metabolized to inactive metabolites. Ten percent of the substance is excreted unchanged in the urine. Changes in amlodipine plasma concentration are not correlated with the degree of

renal impairment. In these patients, amlodipine may be administered at the normal dosage. Amlodipine is not dialyzable.

The half-life of hydrochlorothiazide is prolonged in patients with impaired renal function.

4- Hepatic impairment:

After single oral administration, olmesartan AUC values are 6% and 65% higher in mildly and moderately hepatically impaired patients, respectively, than in their corresponding matched healthy controls. The unbound fraction of olmesartan at 2 hours post-dose in healthy subjects, in patients with mild hepatic impairment and in patients with moderate hepatic impairment is 0.26%, 0.34% and 0.41%, respectively.

Following repeated dosing in patients with moderate hepatic impairment, olmesartan mean AUC is again about 65% higher than in matched healthy controls. Olmesartan mean C_{max} values are similar in hepatically-impaired and healthy subjects. Olmesartan medoxomil has not been evaluated in patients with severe hepatic impairment (see sections posology and method of administration and special precautions and warning for use).

Very limited clinical data are available regarding amlodipine administration in patients with hepatic impairment. The clearance of amlodipine is decreased and the half-life is prolonged in patients with impaired hepatic function, resulting in an increase in AUC of about 40% – 60% (see sections posology and method of administration and special precautions and warning for use).

Hepatic impairment does not significantly influence the pharmacokinetics of hydrochlorothiazide.

Pharmaceutical particulars

List of excipients

Averothiazide 20 mg/5 mg/12.5 mg film-coated tablets

Mannitol, povidone k 30, crospovidone XL, microcrystalline cellulose, Hydrophobic Colloidal Anhydrous Silica, magnesium stearate, hypermellose, polyethylene glycol 6000, talc powder, titanium dioxide, polysorbate 80, iron oxide red.

Averothiazide 40 mg/5 mg/12.5 mg film-coated tablets

Mannitol, povidone k 30, crospovidone XL, microcrystalline cellulose, hydrophobic colloidal silica, magnesium stearate, hypermellose, polyethylene glycol 6000, talc powder, titanium dioxide, polysorbate 80, quinolone yellow ,iron oxide red.

Averothiazide 40 mg/10 mg/12.5 mg film-coated tablets

Mannitol, povidone k 30, crospovidone XL, microcrystalline cellulose, hydrophobic colloidal silica, magnesium stearate, hypermellose, polyethylene glycol 6000, talc powder, titanium dioxide, polysorbate 80.

Averothiazide 40 mg/5 mg/25 mg film-coated tablets

Mannitol, povidone k 30, crospovidone XL, microcrystalline cellulose, hydrophobic colloidal silica, magnesium stearate, hypermellose, polyethylene glycol 6000, talc powder, titanium dioxide, polysorbate 80, quinolone yellow.

Storage:

Averothiazide 20 mg/5 mg/12.5 mg film-coated tablets

Averothiazide 40 mg/5 mg/12.5 mg film-coated tablets

Averothiazide 40 mg/10 mg/12.5 mg film-coated tablets

Averothiazide 40 mg/5 mg/25 mg film-coated tablets

All Store at temperature not exceeding 30 ° C, in dry place.

Pack**Averothiazide 20 mg/5 mg/12.5 mg film-coated tablets**

Carton box containing 1 or 2 or 3 (Al/opaque white PVDC) strips each contain 10 film coated tablets + inner leaflet.

Averothiazide 40 mg/5 mg/12.5 mg film-coated tablets

Carton box containing 1 or 2 or 3 (Al/opaque white PVDC) strips each contain 10 film coated tablets + inner leaflet.

Averothiazide 40 mg/10 mg/12.5 mg film-coated tablets

Carton box containing 1 or 2 or 3 (Al/opaque white PVDC) strips each contain 10 film coated tablets + inner leaflet.

Averothiazide 40 mg/5 mg/25 mg film-coated tablets

Carton box containing 1 or 2 or 3 (Al/opaque white PVDC) strips each contain 10 film coated tablets + inner leaflet.

Manufactured by: Averroes Pharma for Pharmaceutical Industries
